Perfluorocarbon Polymer Coating Compositions

We, E.I. DU PONT DE NEMOURS AND COMPANY, a corporation organized and existing under the laws of the State of Delaware, United States of America, of Wilmington, 5 State of Delaware, United States of America, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed to be particularly described in and 10 by the following statement:-

This invention relates to coating compositions and to articles coated therewith. More particularly, this invention relates to modified aqueous dispersion coating compositions 15 having a combination of a perfluorocarbon polymer and a heat-convertible organopolysiloxane resin as the essential organic filmforming materials.

Tetrafluoroethylene polymers character-20 ized by superior heat and chemical resistance have found extensive use as speciality coatings where these properties are particularly important. Another important characteristic of the perfluorocarbon polymer is the release 25 properties, i.e. anti-adhesion or low order of adhesion between the perfluorocarbon poly-

mer and another film-forming material ordinarily adhesive in contact therewith. This property has lead to extensive use of 30 coatings formulated with the perfluorocarbon polymer as anti-stick or release coatings for die molds, extrusion dies, cookie tins, bread pans, and, more recently, non-stick fry pans and other anti-stick cooking 35 utensils.

The aforementioned advantageous characteristics of the perfluorocarbon polymers present significant application problems. Because of the chemical inertness, the per-40 fluorocarbon polymers cannot be ordinarily

applied in solution form for lack of an adequate solvent for the polymer. A convenient method for applying the perfluorocarbon polymer as a coating is in the form of an aqueous suspensoid of colloidal par- 45 ticles thereof. Such an aqueous dispersion is applied to a heat-resistant substrate, the applied coating is dried by volatile loss of water and other ordinarily volatile components of the liquid composition, and the 50 resulting dry coating which ordinarily lacks adequate continuity is heated at an elevated temperature to fuse the deposited particles

of the perfluorocarbon polymer.

The heat resistance of the perfluorocarbon 55 polymer necessitates a high baking temperapolymer necessitates a nigh daking temperature to accomplish fusion of the colloidal particles to a continuous film. With tetrafluoroethylene polymer, baking temperatures are ordinarily in the range of 675°F 60 to 775°F. With interpolymers of hexafluoroethylene propylene and tetrafluoroethylene, such as defined in Specification No. 829,600, somewhat lower baking temperatures can be used, e.g., temperatures ordinarily in the range of 65 550°F to 650°F.

Unless the substrate to be coated initially surface irregularities to promote mechanical anchorage of the perfluorocarbon polymer coating, the substrate is treated 70 either chemically to etch the surface or mechanical anchorage of the coating in compensation for the anti-stick properties of the coating. While anti-adhesion is a desirable characteristic for many purposes, it 75 is a disadvantage for many other potential uses for the perfluorocarbon polymer coat-With composite finishing systems in which the perfluorocarbon polymer coating is the undercoat and another organic coating 80

is applied thereover, the anti-adhesion characteristics of the perfluorocarbon polymer inhibits adequate intercoat anchorage. For example, with electrical assemblies fabricated with wire electrically insulated with a layer of perfluorocarbon polymer, anti-adhesion and lubricity of the insulation present serious handling problems, and it is highly desirable to impregnate or encapsulating varnish or encapsulating composition which adheres to the perfluorocarbon insulation and provides rigidity to the assembly.

Another characteristic of the perfluoro-

15 carbon polymers which is disadvantageous to many uses is softness which permits it to be easily abraded or cut through in hand-

ung.

A further characteristic which is disad20 vantageous is the necessity of applying the coating at a relatively thin dry coating weight, e.g., at a fractional mil coating thickness, and applying a plurality of coats to obtain the desirable useful thickness. Primers 25 having perfluorocarbon polymer as the essential organic film-forming material ordinarily are applied satisfactorily at dry film thickness up to about 6.0 mil per coat. Topcoats are ordinarily applied adequately at about 30 0.5 mil to about 2 mils per coat.

We have found that one or more of the aforementioned disadvantages associated with the use of the perfluorocarbon polymer as a coating material are overcome by suitable modification of the aqueous suspensoid of the perfluorocarbon polymer with a heat-convertible organopolysiloxane resin and chromic acid, and, if desired, an inorganic polybasic oxy-acid of phosphorus or sulphur.

The present invention accordingly comprises a water-dilutable aqueous dispersion coating composition consisting essentially

01:--

55

(A) colloid particles of at least one per-45 fluorocarbon polymer, said polymer being tetrafluoroethylene polymer or hexafluoropropylene/tetrafluoroethylene interpolymer, dispersed in an aqueous continuous phase,

(B) a solution of a heat convertible (as 50 herein defined) organo-polysiloxane resin containing structural units of the formula:

in which R and R', which may be the same or different (and which may vary from one structural unit to another), are monovalent 60 hydrocarbon radicals in a water-immiscible organic solvent therefore as a dispersed phase,

(C) a sufficient quantity of one or more water-soluble anionic surfactants to maintain 65 the stability of the dispersion of the per-

fluorocarbon polymer and the solution of organo-polysiloxane in the continuous aqueous phase, and

(D) chromic acid.

Pigment may be present in the coating 70 composition in proportions up to 500 parts by weight per 100 parts total weight of the perfluorocarbon polymer and the organc-polysiloxane resin.

In the following description, reference is 75 made to the polybasic oxy-acid component and it is to be understood that this essentially comprises chromic acid and may, if desired, additionally include an oxy-acid of phosphorus or sulphur.

Useful proportions of the organopolysiloxane resin are in the range of from 3 parts to 100 parts per 100 parts by weight of the perfluorocarbon polymer, preferably 10-35 parts of the organopolysiloxane resin. 85

Useful proportions of the polybasic inorganic oxy-acid are in the range of from 5 parts to 200 parts by weight, including at least 5 parts of chromic acid, per 100 parts total weight of the perfluorocarbon polymer 90 and the organopolysiloxane resin. However, no significant advantage is seen in using more than 100 parts of the oxy-acids on the indicated basis. Preferred proportions of the oxy-acid are in the range of 20 to 65 95 parts on the indicated basis. The oxy-acid components can be solely chromic acid or oxy-acid mixtures of chromic acid and another of the identified inorganic oxy-acids, which mixture provides at least 5 parts of 100 chromic acid per 100 parts of the perfluorocarbon polymer and the organopolysiloxane resin. Preferably the oxy-acid mixtures contain at least 10 parts of chromic acid per 100 parts by weight of the acid mixture, the 105 mixture being preferably composed of chromic acid and orthophosphoric acid. The orthophosphoric acid is preferably in the proportion of 50 to 150 parts per 100 parts by weight of chromic acid. 110

The total proportion of surfactant component, including surfactant introduced to stabilize the aqueous suspensoid of the perfluorocarbon polymer, surfactant introduced to emulsify or disperse the solution of the organopolysiloxane in the continuous aqueous phase, and surfactant introduced to facilitate dispersing the pigment, ordinarily is at least 3 parts and ordinarily does not exceed 50 parts per 100 parts by weight of the perfluorocarbon polymer. Presence of an anionic surfactant is preferred and it is ordinarily present in the proportion of at least 2 parts per 100 parts of the perfluorocarbon polymer, preferably in the range of 125 5 to 20 parts. A non-ionic surfactant may be present in combination with the anionic surfactant in proportions up to above 40 parts, preferably 5 to 30 parts per 100 parts of the perfluorocarbon polymer. Presence 130

of the non-ionic surfactant provides the aqueous dispersion with an advantageous increase in body.

Aqueous suspensoids of tetrafluoroethy-5 lene polymer useful in this invention are described, for example, in Specification No. 631,570. Concentrated aqueous suspensoids of colloidal particles of tetrafluoroethylene polymer, such as described in Specification 10 No. 631,504, are especially useful as raw materials preparing the coating compositions of this invention. Such aqueous suspensoids are commercially available and ordinarily contain a surfactant, e.g., anionic sodium 15 lauryl sulfate or non-ionic "Triton" X-100 (trade mark) in the proportion of about 2 to 6 parts per 100 parts of the perfluorocarbon polymer as a stabilizer for the suspensoid. Interpolymers of hexafluoropropy-20 lene and tetrafluoroethylene useful in the preparation of the coating compositions of this invention are described in Specification No. 829,600. Aqueous suspensoids of these interpolymers are commercially available 25 and ordinarily contain a non-ionic surfactant, e.g., "Triton" X-100 octylphenoxypolyethanoxyethanol in the proportion of about 3 to 6 parts per 100 parts by weight of the perfluorocarbon interpolymer. Commercially 30 available aqueous suspensoids of these perfluorocarbon polymers ordinarily contain up to about 60% by weight of the polymer.

When mixtures of the perfluorocarbon polymers are used, ordinarily at least 5 parts

When mixtures of the perfluorocarbon polymers are used, ordinarily at least 5 parts 35 of the tetrafluoroethylene polymer and at least 10 parts of the interpolymer are necessary for an effective contribution per 100 parts of the perfluorocarbon polymer mixture.

The heat-convertible organopolysiloxane resin, the second essential component of the coating composition is organic-solvent-soluble in the non-converted state and is water-dispersible. The expression "heat-45 convertible" is used herein in relation to the organopolysiloxane resin, to refer to such resins which, when deposited as a thin coat on a heat-resistant substrate and heated at temperatures in the range of about 2.10°F 50 to about 750°F, yield smooth continuous films which are substantially insoluble in solvents contained in the starting solution of the organopolysiloxane resin. Useful organopolysiloxane resins contain structural units 55 of the formula:

wherein R— and R'— represent monovalent hydrocarbon radicals; the polysiloxane may be, and preferably is, made of up of a combination of a number of structural units of this formula which have dif-

ferent R and R' substituents. The R and R' substituents are usually a combination of alkyl and aryl radicals with methyl-phenylpolysiloxanes being preferred; the preferred polysiloxane resins contain the methyl and 70 phenyl radicals in the proportion of from 1 to 2 per silicon atom in the siloxane molecule. It is also preferred that the methylphenylpolysiloxane resins should contain from 0.5 to 2 methyl substituents per phenyl 75 substituent. Useful organopolysiloxane resins and the process for their preparation are described in U.S. Patent 2,258,222. Organopolysiloxane resins useful in formulating the coating compositions of this 80 invention are commercially available under the following designations: (Dow Corning) DC-801, DC-803, DC-805, DC-806, and DC-840 silicone resins; (General Electric) SR-82, SR-112, SR-02, SF-69 and Silicone 85 Resin 81727; and (Union Carbide and Carbon) Silicone Resins R-62 and R-64.

As indicated hereinbefore, the proportion of organopolysiloxane resin can range up to 100 parts per 100 parts by weight of the per-fluorocarbon polymer, at least 3 parts of organopolysiloxane being required to provide an effective contribution. The preferred proportion is 10 to 35 parts, and while higher proportions up to 100 parts provide useful 95 compositions, they do not usually have the desired balance of properties. In this range of higher proportions of the organopolysiloxane resin, the resulting coating lacks the desired toughness.

The organopolysiloxane resin is ordinarily used in the form of a solution of the resin in a volatile liquid water-immiscible organic solvent for the organopolysiloxane resin. Any organic solvent which is ordinarily 105 used in paint, varnish and lacquer formulations which is a solvent for the organopolysiloxane resin and which is characterized by water-immiscibility to provide dispersibility in water can be used to prepare the 110 solution of the organopolysiloxane resin. Such solvents can be hydrocarbons, esters, ketones, ethers, and mixtures thereof. Hydrocarbons are preferred solvents, e.g., toluol, xylol, benzene, high solvency pet- 115 roleum naphthas, mineral spirits, hexane, cyclohexane, and the like. The solution of the resin can have a content of up to about 75% by weight of the organopolysiloxane resin, the resin concentration ordinarily being 120 in the range of 20 to 60% by weight of the solution. Useful solutions of the resin can have a resin concentration of 10% or even lower when it is desirable to increase the proportion of solvent dispersed in the con- 125 tinuous aqueous phase. Ordinarily the organic solvent does not exceed a proportion of about 40% based on the total weight of the coating composition. Preferred proportions are in the range of 5% to 25%. Use 130

of a high proportion of solvent reflects a reduction in the content of the film-forming components of the coating composition which in turn ordinarily reflects a reduc-

tion in the coating weight per coat.

The third essential component of the aqueous dispersion coating composition is the water-soluble surfactant which includes an anionic surfactant. The useful propor-10 tions of the surfactant are recited hereinbefore. Sodium alkyl sulfates having 10 to 18 carbon atoms in the alkyl substituent are representative for stabilizing the aqueous suspensoid of the perfluorocarbon resin, 15 sodium lauryl and sulfate being especially While the aqueous suspensoid of the perfluorocarbon resin may supply a substantial proportion of the anionic surfactant, the content thereof can be supplemented 20 with additional surfactant which may be anionic or non-ionic. Preferably the supplemental surfactant is a combination of anionic and non-ionic surfactants. The anionic surfactant can be a sodium alkyl sulfate or an 25 alkyl surfonate salt, each having 10 to 18 carbon atoms in the alkyl substitutent, or an alkyl-arylsulfonate, e.g., a dialkylanph-thalene sulfonate having 3 or 4 carbon atoms in each alkyl substituent. Sodium sulfonates 30 of a plurality of naphthene units condensed with formaldehyde are particularly useful as the anionic surfactant for dispersing the pigment in an aqueous medium. Non-ionic surfactants, e.g., "Triton" X-100 octylphen-35 oxypolyethanoxyethanol, are ordinarily preferred in dispersing the pigment in a nonaqueous medium.

Useful non-ionic surfactants which can be included in combination with the anionic 40 surfactants are represented by polyethanoxyethers of alkyl phenols, alcohols or mercaptans, and polyethanoxy esters of hydrophonbic fatty acids and polypropylene ether esters of such fatty acids. Preferred non-45 ionic species are alkylphenoxypolyethanoxyethanols having 7 to 12 carbon atoms in the alkyl substituent and from 8 to 15 moles of ethylene oxide con-

densed per mole of alkylphenol.

The fourth essential component of the coating composition is chromic acid, or a mixture of chromic acid with at least one polybasic oxy-acid of phosphorous or sulfur, such acid mixtures preferably including the 55 tribasic orthophosphoric acid in combina-tion with chromic acid. For calculating purposes, chromic acid as referred to throughout the specification and claims is identified as CrO, which in the aqueous medium yields 60 chromic acid. Typical polybasic acids which can be used in combination with the chromic acid include orthophosphoric, pyrophosphoric, sulfuric and sulfurous acids. These polybasic acids enhance the curing of the 65 organopolysiloxane resin and in crosslinking

the polysiloxane resin, at least a portion of the oxy-acid, especially orthophosphoric and chromic acids, apparently reacts with the polysiloxane resin to become an integral part of the resulting crosslinked resin. While 70 chromic acid can be used as the sole polybasic oxy-acid component, a mixture of chromic acid and the tribasic orthophosphoric acid is preferred. As stated hereinbefore, the proportion of oxy-acid preferably 75 is in the range of 20 to 65 parts per 100 parts total weight of the perfluorocarbon polymer and the organopolysiloxane resin.

Pigments and extenders can be present in the coating composition in proportions up to 80 500 parts per 100 parts total weight of the persiuorocarbon polymer and the organopolysiloxane resin. Useful pigments and extenders are necessarily substantially non-reactive with the oxy-acid component of the 85 composition. Metal oxides, chromates, silicates, sulfates, phosphates, carbon black, colloidal silica and montmorillonite clays are typical materials useful for pigmentation. Metal hydroxide and metal carbonate pig- 90 ments can be used at low acid concentrations where moderate reactivity of the pig-

ment can be tolerated.

Preferred proportions of total pigment range from 10 parts to 150 parts per 100 95 parts total weight of the perfluorocarbon resin and the organopolysiloxane resin. Within the range of up to 50 parts of total pigment, the finished deposited from the coating composition and cured exhibits ad- 100 vantageous retention of properties ordinarily attributed to the presence of the perfluorocarbon resin and further exhibits improved hardness, improved film-build, improved abrasion resistance and improved adhesion. 105 When the pigmentation is in the range above 50 parts, the contribution of the perfluorocarbon polymer to the film properties are proportionately decreased with increasing proportions of pigmentation, but this in-110 crease in pigmentation in combination with the oxy-acid cured organopolysiloxane resin reflects further improvement in film-build, hardness, abrasion resistance, and adhesion. These more highly pigmented compositions 115 are advantageously bondable with other organic coatings which ordinarily do not adhere adequately to tetrafluorocarbon polymer and hexafluoropropylene-tetrafluoroethylene interpolymer substrates.

Still other modifiers in addition to the aforementioned essential components may be present in the coating composition, but their presence is not essential to accomplishment of the objectives of this invention. 125 Bodying agents, e.g., methyl cellulos, dimethyl, dioctyl ammonium bentonite clay, high molecular weight carboxylic vinyl polymers; flow control agents; and other additives can be included in ordinary small pro- 130 portions necessary to accomplish their pur-

Coating compositions of this invention are applicable at concentrations ranging up to 70% by weight of solids, including the oxyacid component as part of the solids content which is deposited from the composition as a finish. The coatings are usually applied at a solids content of at least 20% by weight, 10 preferably at 30% to 60% by weight. However, for some purposes, application at 10% or even as low as 5% by weight is considered to be practical. Inasmuch as the compositions have a continuous aqueous 15 phase and are water-dilutable, water is used to thin high solids compositions to lower concentrations of solids.

The coating compositions of this invention are prepared by blending a preformed 20 solution of the organopolysiloxane resin in a water-immiscible solvent with an aqueous suspensoid of the perfluorocarbon resin in the presence of a water-soluble surfactant including an anionic species to thereby form a 25 dispersion having a continuous aqueous phase and the solution of the organopolysiloxane resin as a dispersed phase, and thereafter blending the inorganic polybasic oxy-acid component with the resulting 30 aqueous dispersion. Preferably, the solution of the organopolysiloxane resin is predispersed in water in the presence of a watersoluble surfactant and the resulting aqueous dispersion is blended with the aqueous sus-35 pensoid of the perfluorocarbon resin. Blending can be by an ordinary means, but high speed mixing and heavy duty mixing usually is avoided because of adverse effects on the stability of the aqueous suspensoid of 40 the perfluorocarbon polymer.

When the composition is pigmented, the pigment is initially dispersed in either an aqueous medium or non-aqueous liquid medium in the presence of a surfactant to 45 facilitate wetting of the pigment. The resulting pigment dispersion is blended with the aqueous dispersion of the solution of the organopolysiloxane resin and the aqueous suspensoid of the perfluorocarbon polymer. 50 Preferably, the pigment is predispersed in a non-aqueous liquid medium comprising essentially a soluble surfactant and a solution of the organopolysiloxane resin in a water-immiscible organic solvent therefor. 55 However, water and the soluble surfactant aione or an aqueous dispersion of the or-

resin can be used as the initial dispersion medium for the pigment. Minimum mechanical working of the aqueous suspensoid of the perfluorocarbon resin is desired for stability reasons and consequently, the pigment preferably is not initially dispersed in the presence of the

ganic solution of the organopolysiloxane

65 aqueous suspensoid of the perfluorocarbon

resin. The preformed aqueous pigment dispersion is merely blended with the aqueous suspensoid.

Ancillary components can be included in either the aqueous suspensoid of the per- 70 fluorocarbon polymer, the aqueous dispersion of the solution of the organopolysiloxane resin, the preformed pigment dis persion, or any combination of these three, according to the ordinary techniques of 75 adding these components. Ordinarily, these ancillary components are modifiers for the aqueous suspensoid of the perfluorocarbon polymer and are added directly thereto or to any combination which includes the suspen- 80 soid.

As indicated hereinbefore, two main categories of compositions evolve from this invention, i.e., those having high retention of the perfluorocarbon polymer characteristics 85 with significant improvements and those in which the improvements predominate with the contribution of the perfluorocarbon polymer being of less importance. An important consideration of the compositions of this 90 invention is that high temperature baking or even heating to fusion temperature of the perfluorocarbon polymer is not necessary to the deposition of useful finishes. The deposited coating will cure by simply air- 95 drying at ambient temperature, e.g., the coatings dry tack-free in one hour at 77°F. Moderate force drying temperatures can be used, e.g., the coatings dry tack-free in 10 minutes at 180°F. In the absence of high 100 temperature baking and the use of fusion temperatures, the resulting finishes do not develop optimum properties attributed to the characteristics of the perfluorocarbon poly-Where these optimum properties are 105 desired, baking temperatures in the range of 675°F to 775°F, preferably 5 to 25 minutes at 750°F, are used to cure compositions in which the perfluorocarbon polymer is tetrafluoroethylene polymer. Somewhat lower 110 temperatures are used when the perfluorocarbon polymer is an interpolymer of hexafluoropropylene and tetrafluoroethylene or mixtures thereof with the tetrafluoroethylene polymer, e.g., baking temperatures in the 115 range of 550°F to 650°F, preferably 5 to 25 minutes at 625°F.

In the absence of fusion of the colloidal particles of the perfluorocarbon polymer in the deposited finish, these particles exist in 120 a film-forming matrix of the cured organopolysiloxane/oxy-acid combination substantially as perfluorocarbon colloidal pigment rather than as film-forming particles material. Such uncoalesced or unfused par- 125 ticles of perfluorocarbon polymer continue to contribute some of their advantageous characteristics to the properties of the finish. Intermediate baking temperatures such as from 250°F to 425°F ordinarily used com- 130°F

mercially for curing conventional baking finishes can be used in curing the finishes of this invention to enhance the cure of the organopolysiloxane resin and facilitate removal of surfactant, but such curing temperatures do not enhance the contribution of the perfluorocarbon polymer in the absence of fusion.

Coating compositions of this invention 10 formulated with a high relative proportion of the perfluorocarbon polymer and low pigmentation or unpigmented, e.g., below about 50 parts of pigment per 100 parts total weight of the perfluorocarbon polymer and 15 the organopolysiloxane resin are preferably cured at a temperature sufficient to fuse the colloidal particles of the perfluorocarbon polymer. With coating compositions of this invention formulated with the perfluoro20 carbon polymer moderately or highly modified with pigment and having substantial proportions of the organopolysiloxane resin as film-forming material, adequate curing is accomplished with ordinary moderate baking 25 temperatures or even by air-drying at ambient temperatures. Baking of these compositions at higher temperatures sufficient to fuse the perfluorocarbon polymer particles does not significantly enhance the properties 30 of the finish contributed by the perfluorocarbon polymer. Advantages of moderate baking over air-drying of the invention coatings reside in enhanced adhesion, hardness,

35 sensitivity. The coating compositions of this invention can be applied by any of the conventional coating techniques such as by spraying, brushing, dipping or roller coating. 40 coating compositions can be applied to any of a wide variety of substrates. While the substrate is preferably heat-resistant, e.g., iron, steel, copper, bronze, brass, nickel, aluminum, tungsten, titanium and alloys of 45 the indicated metals, glass and other ceramic materials, to accommodate fusion temperatures for the perfluorocarbon polymer, innumerable other less heat-resistant substrates, e.g., wood, paper, textiles, rubber 50 synthetic elastomers and the like, can be coated with the invention compositions in consideration of curing the deposited coating composition at moderate baking temperatures or even at ambient temperatures 55 such as 77°F. A limitation is that the substrate be tolerant of exposure to the aqueous

and abrasion resistance and reduced water-

composition containing the oxy-acid.

Compositions of this invention are applicable in substantially thick coats, e.g., up to about 5 mils dry thickness per coat. Such film thicknesses are significantly thicker than are applicable with conventional coatings formulated with aqueous suspensoids of the perfluorocarbon polymer or interpolymers.

The relative increase in thickness is at least

50% greater, the increase ordinarily being 100% or more. These finishes cured at fusion temperature exhibit retention of the desirable properties attributed to the contribution of the fused perfluorocarbon polymer, i.e., heat, chemical, and electrical resistance and durability, when the coating composition is either a clear formulation or pigmented up to about 50 parts of pigment on the indicated basis. In addition, these 75 cured finishes exhibit the advantageous improvements of significantly enhanced hardness, abrasion resistance and adhesion.

Baked finishes and air-dry finishes of the invention compositions in which the proportion of pigment is in the range of 50 to 500 parts, per 100 parts total weight of the perfluorocarbon polymer and the organopolysiolxane resin, exhibit the same advantageous improvements, but the contributive 85 characteristics of the perfluorocarbon polymer are diminished with decreasing relative proportions of the perfluorocarbon polymer.

The complete liquid coating compositions are characterized by limited package stabil- 90 ity, particularly when the proportoin of the oxy-acid component is high. Because of the potential instability, the coating composition is preferably packaged as a two-package combination having a stable 95 aqueous solution of the oxy-acid component in one package and a stable aqueous dispersion constituting the balance of the composition in the second package. Appropriate proportions of the contents of the two pack- 100 ages are simply mixed together to complete the composition. If desired, the composition can be packaged with a greater plurality of component packages which are simply blended to complete the formulation, e.g., a 105 three-package combination is feasible which the aqueous oxy-acid is in one package, the stable aqueous suspensoid of the perfluorocarbon polymer in the second package, and the clear or pigmented aqueous dis- 110 persion of the solution of the organopolysiloxane resin in the third package. In combining the three packages, it is preferred to initially combine packages two and three and then blend in package one, although the 115 acid can be blended separately with either package two or package three before the entire combination is combined.

The following examples are intended to illustrate this invention and not to limit it in 120 any way. Parts and percentages are by weight unless otherwise indicated.

This coating composition is applied as a single thick coat of about 1 mil to the interior surface of an aluminum ice cube tray and the applied coating is cured by heating for about 6 minutes at 725°F. The resulting 70 coating is hard, abrasion-resistant, and adherent to the metal. Another ice cube tray is coated with an ordinary commercially available "Teflon" (trade mark) TFE perfluorocarbon resin primer at about 0.3 mil 75 and topcoat of about 0.7 mil, and cured under the same conditions. The resulting composite coating is relatively soft, is easilyabraded or scratched, and is weakly anchored to the substrate. The combination 80 of primer and topcoat provides about the same coating thickness as the single coat of the invention composition. The two trays are filled with water and placed in a freezer to produce ice. Release properties relative 85 to ice are satisfactory, the Example 1 coating being rated only slightly less effective than the comparative coating.

The composition of Example 1 is applied as a single coat of about 1 mil to the baking 90 surfaces of an electric grill for frying pan-cakes and baking waffles and over a portion of the coated area is applied an ordinary clear coating of tetrafluoroethylene polymer composition. The coatings are cured and 95 fused by heating for about 20 minutes at 725°F. A comparative grill is coated with a two-coat system of ordinary "Teflon" primer and clear "Teflon" topcoat, and over a portion of the coated area is applied 100 a coat of the composition of Example 1. The coatings on the comparative grill are cured under the same conditions. The coated area having solely the cured coating of Example 1 exhibits the same characteris- 105. tics as indicated for the coated ice cube tray, and the coated area having solely the comparative combination primer-topcoat finish exhibits the same deficiencies noted for the ice cube tray similarly coated. An im- 110 proved bondage is observed at the interface between the invention finish and the comparative clear tetrafluoroethylene polymer

Use of the coated grills for frying pancake 115 batter and baking waffles reveals no significant difference in the release properties of the respective coated areas in reference to releasing the baked products from the grills. A particular advantage of the area coated 120 with the Example 1 composition is that it is harder and less easily marked when abraded with a metal spatula or pancake turner in comparison with the area coated with the ordinary perfluorocarbon polymer finish. 125

of the combined first three portions to complete the final composition. The final composition has a useful pot-life of about 6 hours, pot-life to coagulation being about 36

At curing temperatures below about 650°F, the cure of the film depends on a time-temperature reaction between the reactive organopolysiloxane resin and the oxy-10 acids, i.e., chromic and phosphoric acids.

The hardness and hydrophobic properties of the applied coating increase as the time and temperature of the cure is increased up to about 750°F. The coating air-dries satis-15 factorily at ambient temperatures, e.g., 77°F.

At drying temperatures in the range of 70°F to 125°F, hardness, adhesion and hydrophobic properties are improved by exposure of the coating to sunlight or to ultraviolet 20 light.

composite finishes of ordinary topcoats on tetrafluoroethylene polymer applied over the Example 5 composition as a primer unfused, and the composite 25 finish cured at fusion temperature, exhibit good adhesion of the topcoat. Intercoat adhesion is inferior when the primer is initially fused and then topcoated with an ordinary tetrafluoroethylene polymer coating.

The perfluorocarbon interpolymer suspensoid is 55% interpolymer in water commer-60 cially available as "Teflon" TE-9500 perfluorocarbon polymer suspensoid containing about 6 parts of "Triton" X-100 and 0.75 part of fluorocarbon surfactant per 100 parts of the interpolymer. The tetrafluoroethylene 65 polymer suspensoid is at 60% concentration prepared by electrodecantation from the commercially available 34% suspensoid, and having a content of 3 parts of sodium lauryl sulfate per 100 parts of polymer in the aqueous medium.

The first portion is pebble mill ground for 30,000 cycles. The second portion is emulsified, blended with the first portion, and the third portion blended therewith. The fourth portion is blended with the premixed first 75 three portions immediately prior to application.

The ratios of the components are: Perfluorocarbon Polymer Organopolysiloxane Resin 20.0 80 Surfactant 34.5 Oxy-acids 194.0 Pigment 9.2

This composition is sprayed on steel panels at a dry film thickness of about 1 mil 85 and cured by heating for 15 minutes at 750°F. The resulting cured finish is rated as good in reference to adhesion, cohesion, hardness and flexibility and very good in general appearance, exhibiting significant 90 improvement over an ordinary tetrafluoroethylene polymer primer applied at about 0.5 mil thickness.

Example 6A is prepared identical with that of Example 6 except that the ortho- 95 phosphoric acid is omitted. The properties of the resulting finish cured under the same conditions are comparable with those of the Example 6 composition except that adhesion is rated second best, but better than that of 100 the comparative tertafluoroethylene polymer

Example 6B is likewise prepared identical with that of Example 6 except sulfuric acid replaces the orthophosphoric acid. The 105 cured finish from this composition is rated comparable with that from Example 6A, indicating that the dibasic sulfuric acid is not as effective as the tribasic phosphoric acid in combination with the chromic acid.

Example 6C is prepared identical with Example 6 except that the chromic acid is omitted. The cured finish from this composition exhibits good adhesion, but in the absence of the chromic acid, only minor 115 improvement in cohesion, hardness, and flexibility is registered over the ordinary tetrafluoroethylene polymer primer.

Example 6D is prepared identical with the composition of Example 6 except that the 120 chromic acid content is 10 parts. The cured finish from this composition exhibits good adhesion and significant improvement over the Example 6C cured finished in reference to hardness, cohesion and flexibility. 125

WHAT WE CLAIM IS:-1. A water-dilutable aqueous dispersion coating composition consisting essentially of:

(A) colloid particles of at least one perfluorocarbon polymer, said polymer being 130

tetrafluoroethylene polymer or hexafluoropropylene/tetrafluoroethylene interpolymer, dispersed in an aqueous continuous phase.

(B) a solution of a heat-convertible (as berein defined) organo-polysiloxane resin containing structural units of the formula:

40 -Si-O-

in which R and R', which may be the same or different (and which may vary from one structural unit to another), are monovalent hydrocarbon radicals in a water-immiscible organic solvent therefore as a dispersed phase,

(C) a sufficient quantity of one or more water-soluble anionic surfactants to maintain the stability of the dispersion of the perfluorocarbon polymer and the solution of organo-polysiloxane in the continuous aqueous phase, and

(D) chromic acid.
25 2. A coating composition according to claim 1, which also includes one or more non-ionic water-soluble surfactants.

3. A coating composition according to claim 1 or 2, which also includes a poly-30 basic oxy-acid of phosphorus or sulphur.

4. A coating composition according to any of claims 1 to 3 in which from 50% to 100% of the hydrocarbon radicals in the polysiloxane are methyl and phenyl radicals.

5. A coating composition according to any of the polysiloxane are methyl and phenyl radicals.

5 5. A coating composition according to claim 4, in which the ratio of methyl to phenyl radicals in the polysiloxane is from 0.5:1 to 2:1.

6. A coating composition according to any of claims 1 to 5 in which the organopolysiloxane is present in the proportion of from 3 to 100 parts per 100 parts by weight of the perfluorocarbon polymer.

7. A coating composition according to any of claims 1 to 6, containing a mixture of chromic acid and orthophosphoric acid, the proportion of chromic acid being at least 5 parts per 100 parts total weight of the perfluorocarbon polymer and the organo-polysiloxane resin and the total proportion of chromic acid and orthophosphoric acid being up to 200 parts on said basis.

8. A coating composition according to claim 7, in which the oxy-acid mixture consists of 50 to 150 parts of orthophosphoric acid per 100 parts of chromic acid, the total proportion of the two oxy-acids being up to 100 parts on the indicated basis.

9. A coating composition according to any 60 of claims 1 to 8, containing from 3 to 50 parts of surfactant per 100 parts by weight of perfluorocarbon polymer.

10. A coating composition according to any of claims 1 to 9, in which a mixture of 65 a sodium alkyl sulphate and an alkylphen-

oxypolyethanoxyethanol is used as the surfactant.

11. A composition according to any of claims 1 to 10, which also contains up to 500 parts of pigment per 100 parts total 70 weight of the perfluorocarbon polymer and the organopolysiloxane resin.

12. A composition according to claim 11, containing from 10 to 150 parts by weight of pigment on the indicated basis.

13. A coating composition according to claim 1 in which the constituents are present in the following proportions:

(A) Perfluorocarbon Polymer
(B) Organopolysiloxane Resin having structural units of the formula:

R
I
Si
Oin which R and R', which may be the some a wift.

in which R and R', which may be the same or diferent (and which may vary from one structural unit to another) are monovalent hydrocarbon radicals, from 50% to 100% of which one are methyl and phenyl radicals, the ratio of the methyl to phenyl radicals being from 0.5:1

Mixed Surfactant:

(C) Mixed Surfactant:
sodium alkyl sulphate
alkylphenoxypolethanoxyethanol
(D) Chromic acid and, if desired,

10 10 33
5 to 20
5 to 30 105

polybasic oxy-acid of phosphorous or sulphur 20 to 65 the proportion for (D) and (E) being based 110 on 100 parts total weight of (A) along based 110.

on 100 parts total weight of (A) plus (B).

14. A composition according to any of claims 1 to 13, in which a mixture of 5 to 90 parts by weight of tetrafluoroethylene polymer and 95 to 10 parts by weight of 115 hexafluoroethylene/tetrafluoroethylene interpolymer is used as the perfluorocarbon polymer.

15. As an article of manufacture, a heat-resistant substrate having, as a finish there- 126 on, at least one dry coat of the composition claimed in any of claims 1 to 14.

16. As an article of manufacture, a heatresistant substrate having, as a finish thereon, at least one fused dry coat of the composition claimed in any of claims 1 to 14.

17. As an article of manufacture, a heat-resistant substrate having a dry coat of the composition claimed in any of claims 1 to 14 as a primer coat, and superimposed there- 130

on, at least one dry coat of a coating composition comprising a heat-convertible resin as the essential organic film-forming material. 18. A method of preparing a coating 5 composition which comprises mixing a solution of a heat-convertible as herein defined organopolysiloxane resin in a water-immiscible solvent therefor with water in the presence of a surfactant, thereby forming a 10 dispersion of said solution of resin as the dispersed phase in a continuous aqueous phase, blending the resulting aqueous dispersion with an aqueous suspensoid of colloidal particles of a perfluorocarbon poly-15 mer, said polymer being tetrafluoroethylene polymer or hexafluoropropylene/tetrafluoroethylene interpolymer, in the presence of an anionic surfactant, and thereafter blending chromic acid and, if desired, a polybasic 20 oxy-acid of phosphorus or sulphur, the

essential components being in the proportion of:

Parts by Weight

25 (A) Perfluorocarbon Polymer
(B) Organopolysiloxane Resin
(C) Surfactant, including at least 2 parts of anionic

species 3 to 50
30 (D) Chromic acid, and if
present, other oxy-acid 5 to 200
the proportion of oxy-acid being based on
100 parts total weight of (A) plus (B).

19. A method according to claim 18 which includes the further step of dispersing pigment in a liquid medium in the presence of a surfactant soluble in the liquid medium and blending the resulting dispersed pigment with the aqueous dispersion of the solution of said organopolysiloxane resin and the 40 aqueous suspensoid of said perfluorocarbon polymer, the proportion of pigment being up to 500 parts by weight per 100 parts total weight of said perfluorocarbon polymer and said organopolysiloxane resin.

20. A method according to claim 19, in which said pigment is dispersed in a solution of said organopolysiloxane resin in a water-immiscible organic solvent therefor and containing a soluble surfactant.

21. A water-dilutable aqueous dispersion coating composition according to claim 1 substantially as herein described in any of the Examples.

22. A method of preparing a coating composition according to Claim 18 substantially as herein described in any of the Examples.
